

When to Use string vs StringBuilder in C#

Use string when:

- You are working with small or few strings.
 - The string is not modified repeatedly.
 - You prefer clean and readable syntax (using interpolation or concatenation).
 - The string operations are not in performance-critical code.
-

Use StringBuilder when:

- You are performing many string modifications (in loops).
 - You are building a large string dynamically (reports, logs, HTML/XML).
 - You want to avoid memory overhead from creating many intermediate strings.
-

Summary:

Use Case	Choose
Simple operations	string
Frequent modifications	StringBuilder
Readability preferred	string
Performance-sensitive loop	StringBuilder
