

What Is a User-Defined Constructor?

A user-defined constructor is a constructor you explicitly create in a class or struct to control how objects are initialized when they're created.

Role in Initialization:

- Allows setting default or custom values for fields and properties.
 - Ensures the object starts in a valid state.
 - Supports overloading, enabling different ways to create an object.
-

Summary:

A user-defined constructor gives you control over how and what gets initialized, improving code safety, clarity, and flexibility.
